SUBJECT: Problem of Safe Yield of Matilija and Casitas Reservoirs.

Gentlemen:

Some months ago, I requested Richard H. Jamison, Hydraulic Engineer in this office, to prepare a memorandum on Safe Yield of Matilija and Casitas Reservoirs. The request for this memorandum was made because of various inquiries in this office relative to the Safe Yield in the Zone 1 report, which appeared to be somewhat higher than shown in previous water reports. This office does not know exactly how previous figures were arrived at; hence this memorandum was prepared. Due to the illness of Mr. Jamison for two months or more, the preparation of this memorandum was delayed until the present time.

This memorandum is offered for purposes of record and guidance in the possible revision of parts of our water project because of the results of Mr. Jamison's study.

This memorandum is subject to study by all interested parties and this office will cooperate with all parties in showing basic data as well as methods of calculations. Please note that seepage may have been calculated higher than expected but in order to correlate with the Zone 1 report, the same seepage factor was used.

The chart accompanying the report entitled "Graph of Table 17" shows the results of Table 17 both as to water storage, vacant space and overflow. It may be noted that in many cases, overflow occurs in both reservoirs at the same time.

Yours very truly,

Robert L. Ryan

ROBERT L. RYAN, Engineer
Ventura County Flood
Control District

WATER SUPPLY PROJECTS

COYOTE CREEK AND MATILIJJA CREEK

Coyote Creek 11,300 Ac. Ft. project with a safe net yield to the City of 3000 Ac. Ft. per year would cost \$1,414,000, including land at \$237,000. Matilija Creek 6,600 Ac. Ft. project of like safe net yeld to City, with allowance of an annual release of not less than 1800 Ac. Ft. for the rights below, would cost \$1,589,500, including land at \$41,500.

MEMORANDUM

Probable Safe Yield
of
Matilija and Casitas Reservoirs
Prepared by
Richard H. Jamison, Hydr. Engr.
for
Robert L. Ryan, Flood Control Engr.

This memorandum was prepared pursuant to our conversation of six months ago concerning the probable safe yield to be expected from Matilija and Casitas Reservoirs.

The methods used and the tables developed are presented in support of the following conclusions.

CONCLUSIONS

1. Matilija Reservoir

Assuming that the reservoir was full at the beginning of a five year period of low run-off such as that beginning with May, 1927, the probable safe yield is 2800 acre-feet annually.

If the reservoir had been put into operation November, 1927, an annual yield of 2100 acre-feet could have been expected.

2. Casitas Reservoir.

Assuming that the reservoir had been put into operation December 1, 1925, the probable safe yield is 2600 acre-feet annually.

If the reservoir had been put into operation December 1, 1927, an annual yield of 400 acre-feet could have been expected.

3. Evaporation and Seepage.

The amount of evaporation used in this memorandum is believed to be nearly the correct amount. The amount used for seepage is questionable. If the loss by seepage is less than that used, the yield would be greater than that computed.

The actual seepage cannot be obtained until the reservoir is

in operation. In order to obtain a better idea of the seepage factor, it will be necessary to measure the amount of water entering the reservoir, evaporation pans should be installed to determine this factor, a record kept of all releases of water from the reservoir and a record of the elevation of the water surface should be kept. The latter can be done best by installing water stage recorders. Such information is necessary in order to operate the reservoir properly.

4. Care in Operation Necessary.

The reservoirs are small and care must be taken in their operation so that some water will be available at all times, especially if domestic water is to be served.

5. Diversion from Matilija to Casitas.

Information is presented in this memorandum in Table 17, pages 51 to 57, that will be an aid in determining the amount of water to be diverted. No conclusions are presented here in this respect as more study is required. However, if water is diverted to hold the stored water in casitas Reservoir at a high elevation, a large portion of this would be disposed of by evaporation and seepage.

November 15, 1947

Memorandum
on
Probable Safe Yield of Matilija & Casitas Reservoirs.

Evaporation

The probable evaporation from Matilija and Casitas Reservoirs was determined from temperature records obtained at Ojai and from the records of temperature and evaporation obtained at Gibralter and Jameson Reservoirs in Santa Barbara County.

These records are submitted in Table 1, page 11. The average temperatures at Jameson Lake are very close to the average temperatures at Ojai and the general climatic conditions are similar. The average evaporation records at Jameson Lake were used as a base.

The monthly coefficients that are applied to the evaporation from a pan to obtain the evaporation from a lake were obtained from U.S.D.A. bulletin entitled "Evaporation Investigation in Southern California" by Arthur Young, April, 1945.

The annual evaporation obtained by using these data is 41.67 inches or 3.47 feet. However, in using these evaporation figures, the monthly rainfall was also taken into account in analyzing the operation of the reservoir. For instance, if the rainfall in any month was greater than the evaporation for that month, the difference in feet multiplied by the exposed area of the lake, in acres, was considered as acre-feet input to the stored water in the reservoir.

Seepage from Reservoirs

The seepage, if any, from any reservoir is difficult to determine until the reservoir is created. It depends upon the geology of the area. Water may escape entirely from the area

to be served by the reservoir or water may appear in the stream channels below the water surface of the reservoir. If there is such an escape of water when the reservoir is first put into operation, future siltation may reduce it or even stop it. The use of some estimate of loss in this manner, when studying the operation of a reservoir will result in a more conservative figure of safe yield than by not using any estimate.

The amount of seepage used in this memorandum is the same as that used by the Warren Company in their report to Zone 1. The estimated amounts are 0.50 cu. ft. per second per 100 acres of lake surface for Casitas Reservoir and one half this amount for Matilija Reservoir. (See Warren, Zone 1 report, Pages 117 & 118.)

This was converted into feet depth per month per acre and used with the evaporation.

The monthly figures used are shown in Table 2, page 12.

Old Water Rights

Before any water can be stored in Matilija Reservoir, the Old Water Rights must be satisfied. The rights considered here are those with diversion points on the Matilija Creek, North Fork and Ventura River within a mile or two below the dam. There are other water rights farther down the river that may have to be considered later but they are not within the scope of this memorandum.

The rights considered here are as follows:

Rancho Ojai Mutual Water Company - - - - -	- 231 M.I.
Rancho Matilija - - - - -	- 231 M.I.
Rowe - - - - -	- 16 M.I.
Sheldon - - - - -	- 30 M.I.
Soper and others - - - - -	- 22 M.I.
	<u>530 M.I.=</u>
	10.6 sec.ft.

It is believed that this amount of 530 M.I. is very close to the total of all of the Old Rights, but this figure is subject to correction. Sheldon diverts from North Fork but it was necessary to include his diversion in this study.

In order to determine the amount of water to be released, the daily flow of North Fork was plotted against the daily flow in Matilija Creek. An average curve was drawn through these points. From this curve Table 3, page 13 was prepared.

Referring to Table 3, it will be seen that when there is a flow of 8 sec. ft. in Matilija Creek, there is a flow of 2.6 sec. ft. in North Fork. The sum of these equals 10.6 sec. ft. required to meet the demand of the Old Rights. When the flow increases, enough water must be released from the reservoir, which released water when added to the flow in North Fork will equal 10.6 sec. ft. When there is a flow of 34 sec. ft. in Matilija Creek, it will not be necessary to release any water from storage because there will be enough water in North Fork to meet the demand of the Old Rights.

With flows of 8 sec. ft. and below 8 sec. ft. the Old Rights are entitled to all. The amount to be released during the low flow period will be determined by the relation of the flow in Matilija Creek at elevation 1145 (above the dam) to that at the gaging station, below the dam. We have made many stream flow measurements at both points to determine this relation.

Run-Off Available for Storage in Matilija Reservoir

In order to determine the amount of water for storage in Matilija Reservoir, the daily discharge for each month and the daily rainfall records were studied. From these data the amount of water required to satisfy the Old Rights was determined. This

estimated monthly demand is shown in Table 4, page 14.

These monthly demands were then subtracted from the monthly run-off to obtain the amount of water that could be stored monthly. The amounts available for storage are shown in Table 5, page 15.

Run-off Available for Storage in Casitas Reservoir

Water Rights, if any, below Casitas Dam were not considered in determining the run-off available for storage in Casitas Reservoir. There may be some claims, but if there are, they are believed to be small.

The monthly run-off is shown in Table 6, page 16.

Monthly Distribution of Demand on Matilija Reservoir

In order to determine the monthly demand, the records of the Thermal Belt Water Company in Santa Paula were obtained for the period 1927 to 1947. This company serves both domestic water and water for irrigation.

The monthly demand of this company was converted into percent of the total demand for each year. These percents of the annual demand were then applied to the various annual demands assumed at Matilija Reservoir.

The monthly distribution in acre-feet is shown in the following tables.

For 2100 acre-feet, in Table 7, page 17.

For 2800 " " in Table 8, page 18.

For 3000 " " in Table 9, pages 19 & 20.

The monthly distribution at Casitas Reservoir is based on the probable average percent of the total demand.

The monthly demands, in acre-feet, are shown in Table 10, page 21.

Operation of Matilija Reservoir

A table was prepared showing the area of the surface of the lake for any given capacity. The table is not shown in this memorandum.

With the capacity-area table and the information shown in the preceding tables, the operation of the reservoir by months was set up.

The operation was started with the reservoir full, 7000 acre-feet on May 1, 1927. An annual draft of 4000 acre-feet was first used and it was found that the reservoir became dry a few years later.

An annual draft of 3000 acre-feet was then used and the operation was carried through to October, 1946. This operation is shown in Table 11, pages 22 to 28.

This draft of 3000 acre-feet carried through the dry period without the reservoir going dry, but there were only 370 acre-feet in storage at the end of November, 1931, of which 250 acre-feet are not available, because this amount is below the outlet. The run-off during the winter of 1931-32 filled the reservoir and water was wasted. However, an available supply of 120 acre-feet is dangerously low.

It was then assumed that a year like 1928-29 followed 1931. This is not an unreasonable assumption.

Assuming a year like 1928-29 to follow 1931 gives a period of five years in succession of low run-off. Such a period occurred during the decade 1890 to 1900.

The operation, with 3000 acre-feet draft, was carried through on this assumption (See Table 12, page 29), and it

was found that the water was below the outlet on or about the middle of the following November.

A draft of 2800 acre-feet was then used and it was again assumed that a year like 1928-29 followed 1931. See Table 13, pages 30 & 31. It was found that by the end of the following December there were 686 acre-feet, of which 436 acre-feet were available through the outlet. This is not as much as is desirable for the low point.

It was then assumed that the dam was finished and ready to store water November 1, 1927, with the water surface at the outlet elevation, that is, with the reservoir empty for available storage.

The operation was carried out with a draft of 2100 acre-feet. See Table 14, pages 32 & 33. The available storage was 277 acre-feet at the end of November, 1927. The winter of 1931-32 filled the reservoir. If a year like 1928-29 had followed 1931, there would have been 625 acre-feet of water above the outlet.

Operation of Casitas Reservoir.

A study was made of the operation of Casitas Reservoir similar to the study that was made for Matilija Reservoir.

An annual draft of 4000 acre-feet was used first. It was found that the reservoir became dry in July, 1931.

An annual draft of 3000 acre-feet was used next. This operation was carried through from December, 1925, to October, 1946. See Table 15, pages 34 to 41.

The reservoir was assumed to be empty or at the outlet on December 1, 1925, but by May 1, 1927, the supply had increased to 21,543 acre-feet. There were only 957 acre-feet of vacant storage

space. The inflow during the next four years was small. The draft and evaporation and seepage during this period reduced the amount of water stored to 2444 acre-feet by the end of November, 1931. This 2444 acre-feet appears to be a safe amount for hold-over.

However, it was assumed that a year like 1927-28 followed 1931, and that an annual draft of 3000 acre-feet was continued. This was using a five year period of low run-off. It was found that the reservoir would have been empty sometime during the following October. See Table 16, page 42.

With the same five year period assumption, an annual draft of 2800 acre-feet was used. See Table 16A, page 43 to page 45. It was found that there were only 392 acre-feet in the reservoir at the end of the assumed dry period.

An annual draft of 2600 acre-feet was then used for the same five year period. See Table 16B, page 46 to page 48. There was a gain of ~~873~~ acre-feet in the amount of the stored water at the end of the five year period over that when a draft of 2800 acre-feet was used.

Because we are presumed to be entering a dry period, the probable yield to be expected for such a condition was studied. The same five year period of low run-off was used, except it was assumed the reservoir began to store water in December, 1927.

An annual draft of 400 acre-feet was used. The operation is shown in Table 16C, pages 49 & 50. An inspection of this table shows that the amount of stored water was dangerously low near the end of every year, even with this meager annual draft.

Diversion from Matilija Reservoir to Casitas Reservoir

It is the writer's understanding that the Matilija Dam and Reservoir is a conservation project and not a diversion dam for Casitas Reservoir. If this is true, then the only water available for Casitas Reservoir is that which would flow over Matilija Dam.

The water sheds tributary to the two reservoirs are adjacent. When the run-off of one is low, the run-off of the other is low and when the run-off of the one is high, the run-off of the other is high. In order to understand this relation, the operations of the two reservoirs have been set up side by side in Table 17, pages 51 to 57.

This table shows the amount of stored water at the beginning of the month and the amount of overflow during the month at Matilija Reservoir. It also shows the amount of stored water, the vacant storage space and the over-flow at Casitas Reservoir.

Referring to Table 17, it can be seen that from May, 1927, to February, 1932, a period of about five years, there was available for diversion only 585 acre-feet. Also it can be seen that the floods of February, March and April, 1932, produced 15,850 acre-feet of overflow at Matilija Dam while there was only 6985 acre-feet of vacant storage space in Casitas Reservoir to receive it.

A more thorough study of this table is necessary before deciding upon the size of the pipe line to Casitas Reservoir.
